

Fuel needed to run a 100-W light bulb for one year (876 kWh, or 3153.6 MJ)

(The fuel quantities below assume 100% conversion efficiency. As most power generation/distribution systems only achieve 30% - 35% efficiency, the actual quantity of fuel used to power a 100 W light bulb in your home will be about three times the quantity shown.)

- 166 kg of wood
- 117 to 210 kg (257 to 462 lb) of coal
- 73.34 kg (161.6 lb) of kerosene
- 78.8m³, of natural gas
- 58 kg of Methane
- .006 kg (.014 lb) of uranium

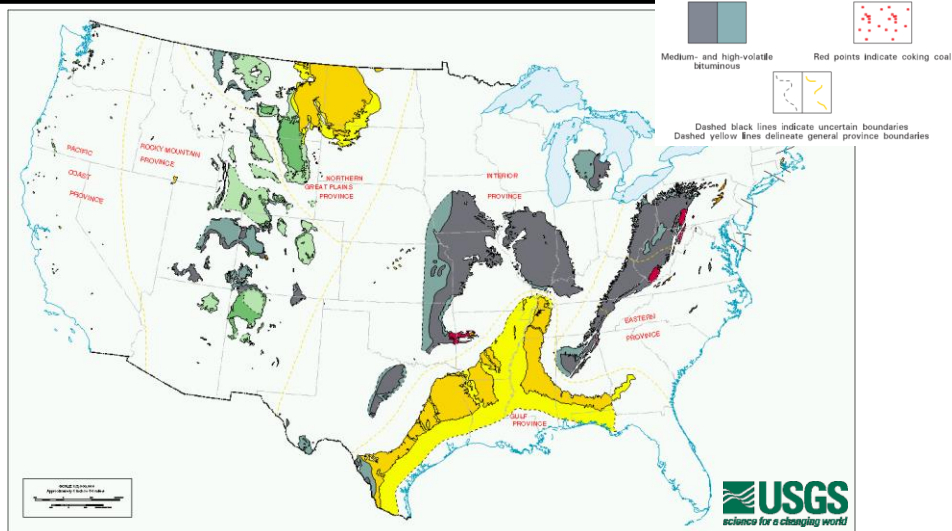

Types of Coal (in order of C Content)

- Anthracite
 - Carbon content (86-98%); Heat value = 15,000 BTUs/lb
 - Most frequently associated with home heating
 - 7.3 billion tons of reserves in the U.S.; mostly in 11 northeastern PA counties
- Bituminous
 - Carbon content = 45-86%; Heat value = 10,500 – 15,500 BTUs/lb
 - Most frequently used to generate electricity and make coke for steel industry
 - Most plentiful form of coal in U.S.
- Sub-bituminous
 - Carbon content = 35-45%; Heat value = 8,300 – 13,000 BTUs/lb
 - Lower sulfur content than other types = cleaner burning
 - Reserves in half-dozen Western US states and Alaska
- Lignite
 - Carbon content = 25-35%; Heat value = 4,000-8,300 BTUs/lb
 - Mainly used for electric power generation
 - Sometimes called brown coal; Geologically young

U.S. Coal Regions

U.S. Proved recoverable coal reserves at the end of 2006

- 111,338 million tonnes of Bituminous & Anthracite
- 135,035 million tonnes of Sub-Bituminous & lignite

The Future of Coal, MIT, 2007

But...

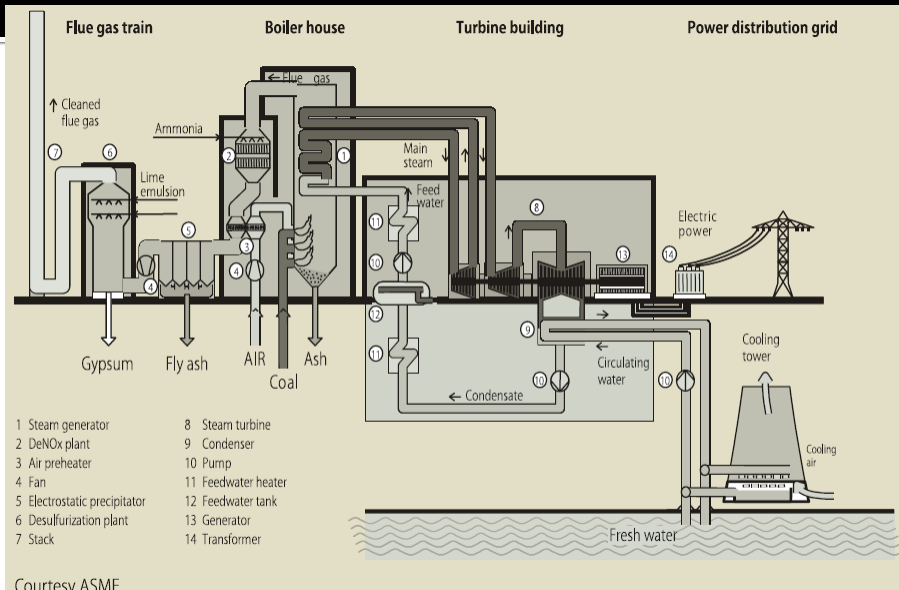

- Carbon intensity of Coal is Very High (92g CO₂/MJ)
- One typical plant = 3 million tons/year CO₂
- US produces 1.5 billion tons/year from coal burning power plants
- If 60% of the US CO₂ from coal were captured for sequestration, it would be **20 million barrels a day**

NATURE | 4 SEPTEMBER 2007

NEWS

Natural gas back in favour with US power companies

Electric utilities in the United States are quickly shifting their sights from coal to natural gas as the lower risk fuel wins the race for the nation's carbon policy to be decided.

Recent proposals to build coal-fired power plants have been met with a barrage of public and political opposition in Texas, Kansas, Florida, Tennessee and elsewhere — including a \$1-billion lawsuit filed by investors of Wall Street's leading investment bank — increasingly worried about the impact of greenhouse-gas regulations in the coming years.

“It’s not the rising price of materials like steel and concrete, which are driving up construction costs, and coal no longer looks like a safe investment if it did just a few years ago. This new calculus hit home in 2007,” says a plan for more than 100 coal-fired power plants were canceled, according to consulting firm Global Energy Decision, based in Boulder, Colorado. In their place, experts say, utilities are turning to natural gas as a quicker, cheaper and lower-emission alternative to meet growing demand while lawmakers sort out national carbon policy.

“Over the past year to two years there has been this 180-degree turn from concern about dependence on natural gas to concern about climate change,” says Larry Mikora, an energy analyst and senior power adviser at Cambridge Energy Research Associates in Massachusetts. “The US power sector started to move back towards natural gas very substantially.”

Cheaper-burning natural gas became fuel of choice for new electricity generators in the 1990s, but increased demand along with peaking production in many US gas fields caused prices to spike in 2002. At about \$10 per million British thermal units, today’s prices are more than triple the average throughout the 1990s. Building more natural gas plants could drive prices even higher — and make the nation that much more dependent on imports, which are already on the rise. Coal currently provides almost half of the nation’s electricity, and is one of the few domestic energy resources that remains abundant. Utilities also use coal, along with nuclear power and natural gas, as a critical source of carbon-based power.

But given the ever-upping costs and lack of certainty about long-term economics owing to impending climate regulation, neither coal nor nuclear power looks terribly attractive from an economic standpoint at the moment, says Erika Lujan, a researcher at the Electric Power

Carbon burial buried

The US Department of Energy has pulled out of a flagship project to build the first ‘clean’ coal-fired power plant in the United States, a move that will kill the project unless supporters can rouse Congress on its behalf.

The FutureGen project was intended to demonstrate technologies for capturing and burying carbon dioxide from coal-fuelled power plants; it was

doubled to \$1.8 billion in recent years, and last week the department pulled out of the deal after failing to reach a new funding agreement with its private partner, the FutureGen Industrial Alliance, which consists of more than a dozen energy companies. The energy department had been slated to pick up three-quarters of the bill for the 275-megawatt plant. “I’m disappointed because

Soaring costs mean the FutureGen power plant may never be built.

says Howard Herzog, a carbon-sequestration expert at the

“It’s hard for me to see this not delaying overall progress.”

In the project’s place, the administration says it will help companies add carbon-capture and -sequestration equipment to new or existing coal plants that have at least 300 megawatts of capacity. Officials say this will ultimately save taxpayers money while allowing the technology to spread more quickly. The abrupt decision has infuriated

BUSINESS

King coal constrained

Sustained high oil prices won’t be enough to make coal liquefaction economically viable without large-scale public investment. Katharine Sanderson reports.

Economic isolation forced South Africa to refine the coal technology used today at Secunda, Mpumalanga.

Spremberg, Germany

- First test plant for CCS
- 30 MW plant, cost \$70m Euros
 - U.S. Average = 976 MW
- CO₂ separated, condensed, transported to gas field, forced 1,000 m underground
- Larger demonstration project slated for 2015

Conclusions

- World power demands are expected to rise 60% by 2030.
- Coal is a huge part of global energy use and is likely to remain important
- Technology exists to remove 90% of CO₂, 99% of sulfur dioxide, 99% of particulates, and 90% No_x
- Costs of implementing these technologies are large and possibly prohibitive
